Chapter 1 Introduction

1.1 Dial Routing Interface

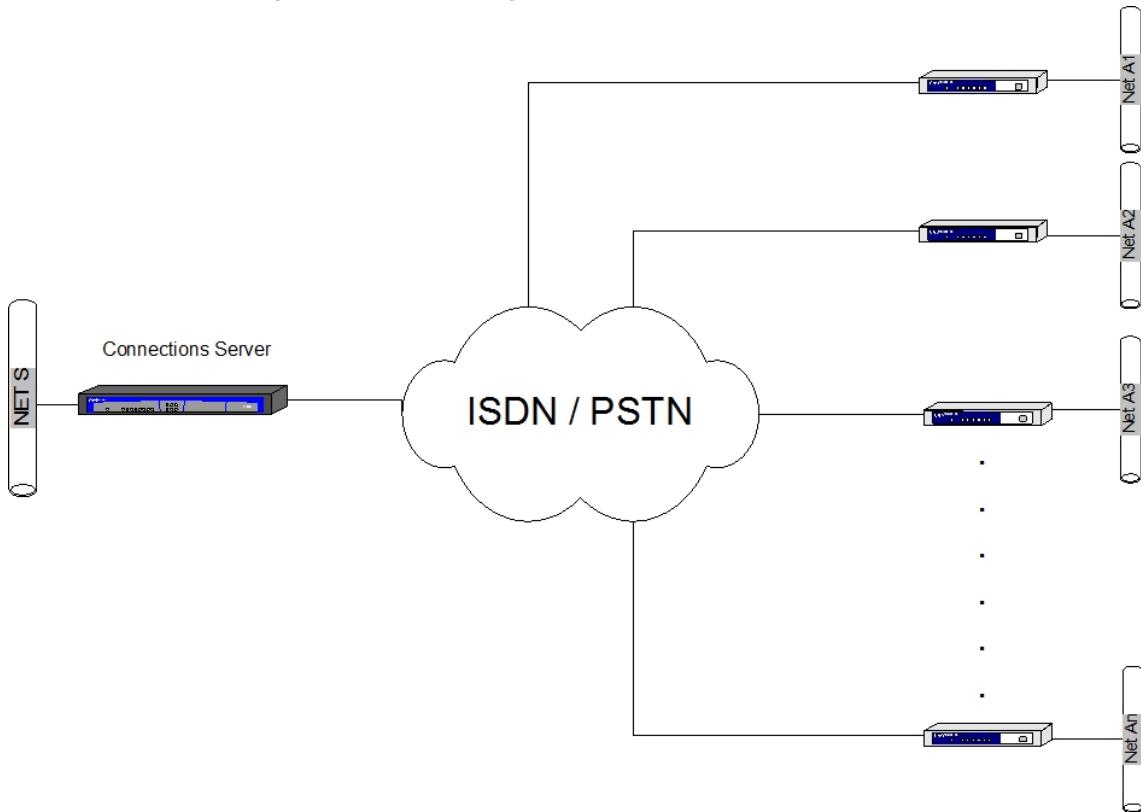

The *Dial Routing* interface is a virtual interface that distributes IP traffic via a pool of PPP Dial interfaces. A series of connections is defined in the configuration of said interface such as the PPP Dial interfaces pool name. Each profile has an identifier (ID), which uniquely identifies this and a set of associated parameters (called number, user and password). Each PPP Dial interface can be registered in the pool through configuration. On enabling the *Dial Routing* feature, enter the pool name configured in the *Dial Routing* interface.

1.2 Static Route ID

The ID static routes are static routes with a *Dial Routing* interface as their next hop and an extra parameter: the ID (profile identifier). Default is cost 3 assigned.

1.3 Function

Through the combination of the static route IDs and the *Dial Routing* interface, the router can act as a PPP Dial connection server. Supposing we have the following network:

In the connection server, you add the same number of route IDs as there are BRANCH networks. In the example, supposing we add a route to the LAN network of each branch (A1, A2An). If a device located in network S needs to address branch X's LAN (AX), the IP packets exit with source S and destination AX and reach the connection server in the first hop. In the initial state, assuming that an alternative lower cost route to said destination network does not exist, the first IP packet uses the route ID. This packet passes to the specified *Dial Routing* interface in the next route hop together with the ID. The *Dial Routing* interface then checks if said ID is in use and if not, searches for a free PPP Dial interface (from those registered). If one is found, it reserves it, dynamically configures it with the ID profile parameters and runs it over all the ID routes whose next hop is the *Dial Routing* interface whose ID is the previous ID. This then adds a static route (dynamically created) to each with the same destination and mask, the next hop being the reserved PPP Dial interface (with cost 1). The rest of the IP packets use the new static route. When the call is released (due to idle timeout or something similar), this new static route disappears.

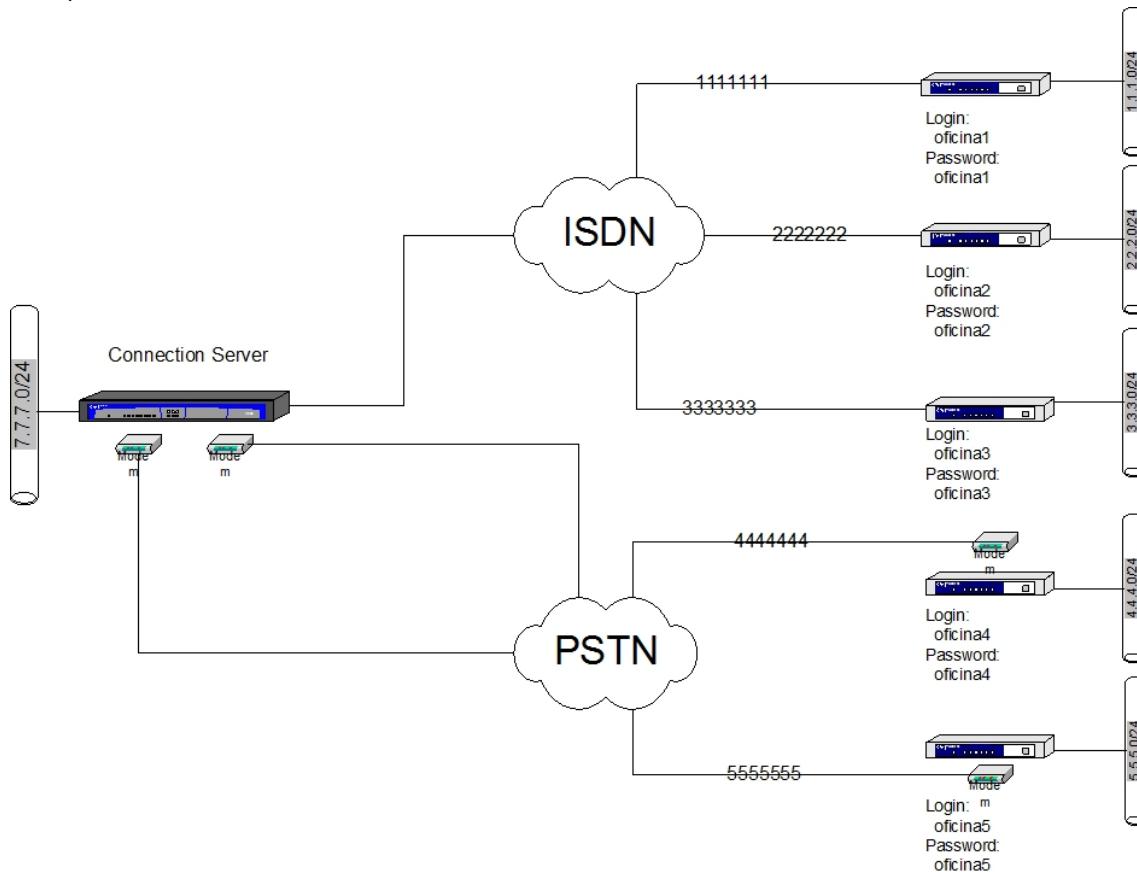

1.4 Configuring correctly

- Create the same number of PPP interfaces as B channels or modem connections you wish to reserve for the connections (create as many simultaneous connections as you wish).
- Create the *Dial Routing* interface.
- From the *Dial Routing* interface configuration, add as many connections as there are different destinations. Each profile is composed of a unique identifier, an ISDN telephone number, a login and a password; these parameters must be the parameters of the branch they represent.
- From the *Dial Routing* interface configuration, configure the connection pool name.
- From the configuration for each PPP Dial interface you wish to participate in the pool, enable the *Dial Routing* facility and configure the same pool name as assigned in the previous step.
- Add unnumbered addresses to the PPP and *Dial Routing* interfaces. Configure the internal IP address. Enable IP Classless.
- Add static routes ID: destination and mask corresponding to each branch's network next hop the *Dial Routing* interface and ID corresponding to the profile associated with said branch.
- If a particular branch has more than one network, configure the same number of routes (with the same ID) as there are different networks pertaining to the branch.

Configuration of the connections and the routes ID is dynamic: you do not need to restart the device.

1.5 Configuration Procedure

The following example shows the sequence to follow to establish a suitable configuration for a typical scenario, e.g., to access networks located through PSTN and ISDN connections. The figure here shows the user scenario for the example.

The steps to configure the connection server shown in the above graphic are as follows:

In this example, we start from the router default configuration, which acts as the connection server (although you can use any router that possesses this function).

1.5.1 Creating interfaces

The first step is to decide which interfaces are required for said scenario:

- Configure as AT interfaces, the same number of serial lines as simultaneous connections to PSTN destinations required. (without exceeding the number of modems available). Then create a PPP interface for each AT interface. The example shows two modems and we assume we are going to use both. So, configure lines 1 and 2 as AT interfaces and add two PPP interfaces to operate over the AT interfaces.
- Create the same number of PPP interfaces as simultaneous connections to ISDN destinations required (without exceeding the number of ISDN B channels available). This example shows a BRI interface with two B channels and we assume we are going to use both. Therefore, create two further PPP interfaces to operate over the two BRI interface B channels. (Note: more connections can be configured – objective of dial-routing – however we have limited them to two simultaneous ones for this example).
- Additionally, configure a *Dial Routing* interface to manage the PSTN connections using the PPP interfaces that operate over AT, and another one, to manage connections with ISDN destinations using the PPPs configured to operate over the BRI interface.

In short, configure lines 1 and 2 as AT interfaces and add four PPP interfaces and two *Dial Routing* interfaces.

Run **show config** to view the device configuration in text mode. At the end of the configuration text, you can see which interfaces are already available and which ones need changes made to them.

```
*config

Config>show config

ethernet0/0    LAN1          Fast Ethernet interface
serial0/0      SERIAL0/WAN1  X25
serial0/1      SERIAL1/WAN2  X25
serial0/2      SERIAL2/WAN3  X25
bri0/0         BRI/ISDN1    ISDN Basic Rate Int
x25-node       ---           Router->Node
Config>
```

As you can see, the serial lines are in X.25 mode so need changing. As there are no PPP or *Dial Routing* interfaces, these will also have to be added.

The following sequence of commands shows how to execute this operation. Firstly add the PPP interfaces.

```
Config>add device ppp 1
Config>add device ppp 2
Config>add device ppp 3
```

```
Config>add device ppp 4
Config>list devices

Interface      Connector      Type of interface
ethernet0/0    LAN1          Fast Ethernet interface
serial0/0      SERIAL0/WAN1  X25
serial0/1      SERIAL1/WAN2  X25
serial0/2      SERIAL2/WAN3  X25
bri0/0         BRI/ISDN1    ISDN Basic Rate Int
x25-node       ---           Router->Node
ppp1           ---           Generic PPP

ppp3           ---           Generic PPP
ppp4           ---           Generic PPP
Config>
```

Subsequently, create the *Dial Routing* interfaces.

```
Config>add device dial-routing 1
Config>add device dial-routing 2
Config>list devices

Interface      Connector      Type of interface
ethernet0/0    LAN1          Fast Ethernet interface
serial0/0      SERIAL0/WAN1  X25
serial0/1      SERIAL1/WAN2  X25
serial0/2      SERIAL2/WAN3  X25
bri0/0         BRI/ISDN1    ISDN Basic Rate Int
x25-node       ---           Router->Node

1.5.2 Configuring the Dial Routing Interfaces

Dial Routing interface configuration consists of two main steps.

The first is to configure the name of the Pool corresponding to the interface. This pool name links the interface with the PPP interfaces used to carry out the connections. This must be the same as the one configured when enabling *Dial Routing* in the PPP interfaces.

The second is to configure the connection destinations to be carried out through this interface.

You can also configure a time period where a PPP interface remains in quarantine (i.e., without being used by the *Dial Routing* interface) when a local error occurs (failure to establish the physical level in the ISDN interface, for example).

The following shows how to configure the first two vital parameters. To view all configuration possibilities, please see the section on configuration commands further on in this manual.

1.5.2.1 Configuring the Pool name

As already indicated, you need to configure a pool name that refers to the PPP interfaces to “register” these in a *Dial Routing* interface on start up. The command used to configure this is displayed below where we configure “ISDN” as the pool name (so the *Dial Routing* interface manages the ISDN connections) and “PSTN” (for managing connections via the modem).

```
Config>network dialroute1

-- DR interface configuration --
dialroute1 config>pool-name RDSI
dialroute1 config>list interface
Interface Configuration
-----
Pool Name:      RDSI
Quarantine time: 4 min.
dialroute1 config>exit
Config>network dialroute2
-- DR interface configuration --
dialroute2 config> pool-name RTC
dialroute2 config>list interface
Interface Configuration
-----
Pool Name:      RTC
Quarantine time: 4 min.
dialroute2 config>
```

The following list shows the router's global configuration once this operation is complete.

```

;
```

```

pool-name RTC
;
exit
;
;
;
dump-command-errors
end
; --- end ---
Config>
```

1.5.2.2 Configuring the destination connections

The second step is to configure the parameters needed to connect to each possible destination. For each destination, configure a telephone number, a user and a password, which shape the profile for this destination.

In the following example, we have five connection destinations (as many connections as remote branches) with the following parameters:

- ISDN Destinations:

Profile 1: telephone number 1111111, user oficina1 and password oficina1.

Profile 2: telephone number 2222222, user oficina2 and password oficina2.

Profile 3: telephone number 3333333, user oficina3 and password oficina3.

- PSTN Destinations:

Profile 1: telephone number 4444444, user oficina4 and password oficina4.

Profile 2: telephone number 5555555, user oficina5 and password oficina5.

The ISDN destination connections are configured in the **dialroute1** interface, which manages the ISDN connections, and the PSTN destinations are configured in the **dialroute2** interface.

The following shows all the commands needed to execute said configuration and the list of connections once created.

```

Config>network dialroute1

-- DR interface configuration --
dialroute1 config>connection 1 default
dialroute1 config>connection 1 destination-address 1111111
dialroute1 config>connection 1 username oficina1
dialroute1 config>connection 1 password plain oficina1
dialroute1 config>connection 2 default
dialroute1 config>connection 2 destination-address 2222222
dialroute1 config>connection 2 username oficina2
dialroute1 config>connection 2 password plain oficina2
dialroute1 config>connection 3 default
dialroute1 config>connection 3 destination-address 3333333
dialroute1 config>connection 3 username oficina3
dialroute1 config>connection 3 password plain oficina3
dialroute1 config>list connection

Release	Modification
11.01.09.90.01	The <i>plain</i> , <i>ciphered</i> and <i>ciphered <password></i> <i>unique</i> command options were introduced as of version 11.01.09.90.01
11.01.13	The <i>plain</i> , <i>ciphered</i> and <i>ciphered <password></i> <i>unique</i> command options were introduced as of version 11.01.13
11.02.02	The <i>plain</i> , <i>ciphered</i> and <i>ciphered <password></i> <i>unique</i> command options were introduced as of version 11.02.02
11.01.09.90.01	The "1.64 chars" option is obsolete in version 11.01.09.90.01
11.01.13	The "1.64 chars" option is obsolete as of version 11.01.13
11.02.02	The "1.64 chars" option is obsolete as of version 11.02.02

1.5.3 Configuring the AT Interfaces

A possible next step would be to configure the AT interfaces so the installed modems operate correctly. The necessary parameters are as follows:

- Speed: Possible speeds are: 2400, 4800, 9600, 19200, 38400, 57600 and 115200. We recommend setting the speed just above the speed of your modem. That is, if you have a 33.6K modem (33600), set the speed to 38400; if you have a 56K modem then set it to 57600, etc.
- AT Commands: AT command configuration depends on your modem. Most modems operate with the default configuration in the device. Please consult the manufacturers manual for your modem to find out what commands are valid.
- It is also very important to stress that there must be 8 data bits, therefore the **Data bit** parameters should not be modified. It's also quite common for the **Parity** parameter to be set to **NONE** and the **Stop bits** to **1**.

The following shows the command sequence to configure the speed and the AT commands. As you can see, the default configuration has been respected (it is perfectly valid for the modem in the example), however, this serves as an example for the commands' syntax.

```
Config>network 1

-- Interface AT. Configuration --
serial0/0 AT config>?
additional-control-command      Set additional AT commands
connection-mode                 Set connection mode (Dial command or DTR)

**Note**

For further information on AT configuration, please see Teldat manual Dm705-I Generic Serial Interfaces.

1.5.4 Configuring the ISDN Interfaces (BRI)

Here we configure the ISDN base interface. Normally the device's default configuration is adequate (provided its base interface corresponds to the European standards). In this case, we recommend that you do not modify any of the parameters.

For American standards, you need to at least configure the standard and the SPIDs of the two circuits. If you do not know these values, please consult your telecommunications operator.

The following example shows how to configure these two parameters where the standard is set to NI-1 (the most common for American standards).

```
Config>network bri0/0

-- BRI ISDN Configuration --

```

**Note**

For further information on configuring the BRI interface, please see Teldat manual Dm729-I BRI ISDN Interface.

1.5.5 Configuring the PPP Interfaces

PPP interfaces. First create a dial profile, or call profile, for the interfaces. This must be set to PERMIT for outbound calls (the aim of *Dial Routing* is to make calls to destinations using a limited number of PPP interfaces). If you want the interfaces to receive calls, create a single dial profile used by all the interfaces. If you want only a few PPP links to receive calls (so the rest of the PPP interfaces only make calls) then create a profile with inbound and outbound calls enabled and another profile with outbound calls only.

The following command sequence shows how to create a dial profile. The example assumes all the profiles can make and receive calls. Create a profile (DIALROUTING) to be used by all PPP links.

```
Config>global-profiles dial

-- Dial Profiles Configuration --
Dial Profiles config>profile DIALROUTING default
Dial Profiles config>profile DIALROUTING inout
Dial Profiles config>profile DIALROUTING idle-time 70
Dial Profiles config>list

DIAL PROFILE..: DIALROUTING
Local Address.:
Remote Address:                               Alternative Remote:
Permissions...: Inbound & Outbound
Idle Time.....: 70
Shutdown Calls: Yes
Priority.....: Normal
Callback.....: None
ISDN Call type: Digital unrestricted data
ISDN Class....: 64 Kbps
Hold queue....: 0
3GPP Acc Ctrl.: None
3GPP APN.....: None
3GPP PDPType ..: IP
3GPP CBST.....: 0,0,1
Call Retry....: Disabled
Call List.....: None
```

Dial Profiles config>

Subsequently, link the PPP interfaces with the base interface they operate (BRI or AT). In the example, the ppp1 and ppp2 interfaces are configured to operate over ISDN and interfaces ppp3 and ppp4 to operate over serial lines 0 and 1, respectively.

```
Config>network ppp1

-- Generic PPP User Configuration --
ppp1 config>base-interface

-- Base Interface Configuration --
ppp1 Base IFC config>base-interface bri0/0 255 link
ppp1 Base IFC config>base-interface bri0/0 255 profile DIALROUTING
ppp1 Base IFC config>list

ppp4 Base IFC config>exit
ppp4 GenPPP config>exit
Config>

Consequently, create the PPP configurations. First create the users. Create one user for the remote branch and another for the central.

```
Config>network ppp1

-- Generic PPP User Configuration --
ppp1 config>ppp

-- PPP Configuration --
ppp1 PPP config>authentication allowed-user oficina1 password oficina1
ppp1 PPP config>authentication allowed-user oficina2 password oficina2
ppp1 PPP config>authentication allowed-user oficina3 password oficina3
ppp1 PPP config>authentication sent-user central password central
ppp1 PPP config>exit
ppp1 config>exit
Config>network ppp2

-- Generic PPP User Configuration --
ppp2 config>ppp

-- PPP Configuration --
ppp2 PPP config>authentication allowed-user oficina1 password oficina1
ppp2 PPP config>authentication allowed-user oficina2 password oficina2
ppp2 PPP config>authentication allowed-user oficina3 password oficina3
ppp2 PPP config>authentication sent-user central password central
ppp2 PPP config>exit
ppp2 config>exit
Config>network ppp3

-- Generic PPP User Configuration --
ppp3 config>ppp

-- PPP Configuration --
ppp3 PPP config>authentication allowed-user oficina4 password oficina4
ppp3 PPP config>authentication allowed-user oficina5 password oficina5
ppp3 PPP config>authentication sent-user central password central
ppp3 PPP config>exit
ppp3 config>exit
Config>network ppp4

-- Generic PPP User Configuration --
ppp4 config>ppp

-- PPP Configuration --
ppp4 PPP config>authentication allowed-user oficina4 password oficina4
ppp4 PPP config>authentication allowed-user oficina5 password oficina5
ppp4 PPP config>authentication sent-user central password central
ppp4 PPP config>exit
ppp4 config>exit
Config>
```

Next, enable CHAP authentication (i.e., so a PPP remote end authenticates through CHAP) and configure the *Dial Routing* pool name each PPP interface belongs to. Please note: it is essential that the pool name coincides with the one configured in the corresponding *Dial Routing* interface.

```
Config>network ppp1

-- Generic PPP User Configuration --
ppp1 config>ppp
```

```
-- PPP Configuration --
ppp1 PPP config>authentication chap
ppp1 PPP config>dial-routing-pool RDSI
ppp1 PPP config>exit
ppp1 config>exit
Config>network ppp2

-- Generic PPP User Configuration --
Ppp2 config>ppp

-- PPP Configuration --
ppp2 PPP config>authentication chap
ppp2 PPP config>dial-routing-pool RDSI
ppp2 PPP config>exit
ppp2 config>exit
Config>network ppp3

-- Generic PPP User Configuration --
ppp3 config>ppp

-- PPP Configuration --
ppp3 PPP config>authentication chap
ppp3 PPP config>dial-routing-pool RTC
ppp3 PPP config>exit
ppp3 config>exit
Config>network ppp4

-- Generic PPP User Configuration --
ppp4 config>ppp

-- PPP Configuration --

ppp4 PPP config>authentication chap
ppp4 PPP config>dial-routing-pool RTC
ppp4 PPP config>exit
ppp4 config>exit
```

With this last step, two types of PPP connections have been configured, one for ISDN connections, which request CHAP authentication, accept users corresponding to branches 1, 2 and 3, is a member of the ISDN *Dial Routing* pool and authenticates with the central user. The second one is for PSTN connections, which request CHAP authentication, accepts users corresponding to branches 4 and 5, is a member of the PSTN *Dial Routing* pool and authenticates with the central user.

The following list displays the device's global configuration in text mode after these configuration adjustments have been made.

1.5.5.1 Configuring with multilink PPP

Sometimes you need to connect to a remote device at a higher speed, using the two B channels from the ISDN base interface for example. In these cases, PPP allows various PPP links to be aggregated through a mechanism known as multilink PPP (MP). This facility can be used over any two PPP links. The most common use is described above (join two B channels and achieve a bandwidth of 128 Kbps). However, it is also possible to perform MP over two modem connections provided both ends have two modem connections.

It is possible, in the given scenario, to make use of this mechanism to obtain wider bandwidth connections, however it is important to emphasize certain aspects:

- A PPP will use several channels simultaneously; therefore the number of simultaneous connections is reduced. That is, if we have two ISDN channels available and multilink can be carried out over them, when this facility is in use, you cannot access other remote devices.
- The destination telephone numbers must be the same for all connections participating in the same MP link, since only one telephone number can be configured for *Dial Routing* connections.

Variations of the above scenario can be proposed that involve the use of multilink. The simplest would be to allow all

ISDN destinations, for example, to execute multilink. This means you only need to configure the PPP interfaces involved so that they can operate with multilink.

Another possible variation is where you only need to access some destinations with multilink. This latter configuration means you need to create another *Dial Routing* interface to handle the PPPs that carry out multilink, configuring these PPP interfaces to operate with multilink, and registering the connections with destinations you wish to access with multilink in said *Dial Routing* interface.

The following is the configuration process for the first of these scenarios.

The first step is to modify the configuration of the base interfaces, which use PPP over ISDN, to allow the use of the two BRI channels. For this, execute the following sequence of commands.

```
Config>network ppp1

-- Generic PPP User Configuration --
ppp1 config>base-interface

-- Base Interface Configuration --
ppp1 Base IFC config>base-interface bri0/0 255 number-of-circuits 2

ppp1 Base IFC config>list

  Base Interface      Profile Name      Base Circuit Id  Number of circuits
-----  -----  -----
          bri0/0        bri/0        DIALROUTING          255            2

ppp1 Base IFC config>exit
ppp1 config>exit
Config>network ppp2

-- Generic PPP User Configuration --
ppp2 config>base-interface

-- Base Interface Configuration --
ppp2 Base IFC config>base-interface bri0/0 255 number-of-circuits 2
ppp2 Base IFC config>list

  Base Interface      Profile Name      Base Circuit Id  Number of circuits
-----  -----  -----
          bri0/0        bri/0        DIALROUTING          255            2

ppp2 Base IFC config>
```

Subsequently, configure the multilink parameters in the PPP interfaces that are going to operate with multilink. **We strongly recommend enabling the option that only lets you add new links to the multilink if the PPP has been initiated from our side.** In addition to the basic parameters (enable multilink and the option to add links in outgoing calls only), you can configure the following:

- *Activation Interval*: Period of time that the traffic load on the line must remain above the activation threshold for a new link to be added.
- *Deactivation Interval*: Period of time that the traffic load on the line must remain below the activation threshold before a link can be released.
- *Activation Threshold*: This is the previously mentioned activation threshold.
- *Deactivation Threshold*: This is the previously mentioned deactivation threshold.
- *Traffic Load*: Direction of the traffic taken into account to calculate the amount of traffic on the line (inbound, outbound or both).
- *Max Links per Bundle*: Maximum number of links that can be added to the same multilink.

We recommend leaving the default values for the remaining parameters.

```
Config>network ppp1

-- Generic PPP User Configuration --
ppp1 config>ppp

-- PPP Configuration --
```

```

ppp1 PPP config>multilink enable
ppp1 PPP config>multilink call-out
ppp1 PPP config>multilink activation interval 60
ppp1 PPP config>multilink activation threshold 80
ppp1 PPP config>multilink deactivation interval 90
ppp1 PPP config>multilink deactivation threshold 25
ppp1 PPP config>exit
ppp1 config>exit
Config>network ppp2

-- Generic PPP User Configuration --
ppp2 config>ppp

-- PPP Configuration --
ppp2 PPP config>multilink enable
ppp2 PPP config>multilink call-out
ppp2 PPP config>multilink activation interval 60
ppp2 PPP config>multilink activation threshold 80
ppp2 PPP config>multilink deactivation interval 90
ppp2 PPP config>multilink deactivation threshold 25
ppp2 PPP config>exit
ppp2 config>exit
Config>

```

In this example, a multilink has been configured. This will attempt to add a new link if the line traffic load remains above 80% of the accumulated bandwidth for 60 consecutive seconds and will attempt to eliminate the link if the traffic load remains below 25% of said bandwidth for 90 seconds, taking into account both inbound and outbound traffic. Please note that the percentage of traffic is taken over the whole of the bandwidth the multilink currently has enabled. That is, if there is a single PPP over ISDN, the activation level will be 51.2 Kbps (80% of 64 Kbps) and when there are two links, the deactivation threshold is 32 Kbps (25% of 128 Kbps). We recommend these calculations be made when configuring. Make sure that you do not configure an activation time threshold below the deactivation time, otherwise you will be constantly adding and removing links.

Use the **show config** command to display the configuration in text mode, which will achieve the following result:

```

1.5.6.2 Enabling Ip Classless

```
IP config>classless
IP config>list ip-protocol
Directed broadcasts: enabled
RIP: disabled
OSPF: disabled
Multipath: disabled
Ip classless: enabled
Icmp redirects: enabled
Icmp unreachable: enabled
IP config>
```

1.5.7 Adding ID static routes

This last step configures the routes with an identifier, which links the IP destinations with the *Dial Routing* interface connections. To do this, a route to the destination address/subnet is created with the gateway being the *Dial Routing* interface used for access, together with the identifier corresponding to the *Dial Routing* connection. This connection should be used to connect to the device providing access to said network.

In this example, a route with identifier has been created for branch 1 to network 1.1.1.0, with mask 255.255.255.0, whose gateway is the dialroute1 interface with identifier 1, since this is the connection created with the parameters to access branch 1. A similar process is carried out with the rest of the branches and the result is shown below:

```
IP config>id-route 1.1.1.0 255.255.255.0 dialroute1 1
IP config>id-route 2.2.2.0 255.255.255.0 dialroute1 2
IP config>id-route 3.3.3.0 255.255.255.0 dialroute1 3
IP config>id-route 4.4.4.0 255.255.255.0 dialroute2 4
IP config>id-route 5.5.5.0 255.255.255.0 dialroute2 5
IP config>
```

Note

For further information on configuring IP, please see Teldat manual Dm702-I TCP/IP.

1.5.8 Configuration Summary

Lastly, we are going to display the definitive global device configuration in text mode for our scenario. This configuration can be used as a base to carry out any required modifications and to send the resulting command sequence to the device to obtain the required configuration. **This configuration does not include the multilink configuration.**

Chapter 2 Configuration

2.1 Dial Routing Interface Configuration Commands

This section describes all the commands to configure the *Dial Routing* interface. To access the configuration environment for said interface, proceed as for the rest of the device interfaces, through the **network** command in the device configuration followed by the interface identifier:

```
*config
Config> network dialroutel
-- DR interface configuration --
dialroutel config>
```

There are certain commands that are common for all the device's interfaces. These commands are described in the manual on configuring common interfaces (Teldat Dm772-I Common Configurations for Interfaces).

The following table shows the commands that are specific to this *Dial Routing* interface:

Command	Function
? (HELP)	Lists the commands or their options.
CONNECTION	Configures a connection.
LIST	Lists the current configuration.
NO	Negates a command or establishes its default value.
POOL-NAME	Configures the pool name.
QUARANTINE-TIME	Configures the quarantine time.
EXIT	Returns to the previous prompt.

2.1.1 Configuring connections

2.1.1.1 Adding a new connection

Run **connection** to add a new connection.

```
dialroutel config>connection <id> default
```

This command creates a connection with default values for the different parameters. The way to modify the parameter values is explained further on in this manual.

The **<id>** parameter is a number that uniquely identifies the connection. This connection identifier must be different from those of existing connections. Otherwise, the command will modify the previously configured connection parameters that have said identifier.

Additionally, this identifier serves to link the connection with the IP destination accessed through the connection. For this, the ID static route identifier must match the *Dial Routing* connection identifier (that provides access to the subnet specifying this route).

2.1.1.2 Modifying connection parameters

Once the connection has been created, assign parameter values or change the previously assigned value by running **connection** with the different permitted options.

2.1.1.2.1 Modifying the destination telephone number

```
dialroutel config>connection <id> destination-address <telephone number>
```

2.1.1.2.2 Modifying the user

```
dialroutel config>connection <id> username <name>
```

2.1.1.2.3 Modifying the password

```
dialroutel config>connection <id> password { <plain> | <ciphered> } <password> { <unique> | <cr> }
```

2.1.1.3 Deleting a connection

Deletes a connection, as shown below:

```
dialroutel config>no connection <id>
```

2.1.1.4 Example of a connection configuration

First, create the connection:

```
dialroutel config>connection 5 default
```

Secondly, assign the values to the different parameters:

```
dialroutel config>connection 5 destination-address 918076565
dialroutel config>connection 5 username usuariol
dialroutel config>connection 5 password plain password1
dialroutel config>list connection
Connections
-----
ID      Destination Address   Username
-----
5      918076565           usuariol
dialroutel config>
```

It may be necessary to change the value of an incorrectly entered parameter. For example, if it is necessary to insert a 0 in front of the telephone number in order to access the external line, the command is as follows:

```
dialroutel config>connection 5 destination-address 0918076565
dialroutel config>list connection
Connections
-----
ID      Destination Address   Username
-----
5      0918076565           usuariol
dialroutel config>
```

Lastly, when you wish to delete a connection, enter:

```
dialroutel config>no connection 5
dialroutel config>list connection
No connections found.
dialroutel config>
```

2.1.2 Configuring the pool name

The connection pool name is used to link the *Dial Routing* interface with the PPP interfaces used to establish the connections. For this, on enabling *Dial Routing* in the corresponding PPP interfaces, configure the same profile name as configured here.

To configure the PPP link pool name that will use this interface, run the following command:

```
dialroutel config>pool-name <pool-name>
```

Example:

```
dialroutel config>pool-name POOL1
dialroutel config>
```

2.1.3 Configuring the quarantine time

When a PPP interface suffers a local source error detectable only when you try and carry out a connection (ISDN cable disconnection for example), a mechanism is used to avoid successive unsuccessful attempts to use said interface. This mechanism places the interface in *quarantine* for a given period of time during which the *Dial Routing* will not use said PPP link. The duration of this quarantine period is configurable through the following command:

```
dialroutel config>quarantine-time <number of minutes>
```

Example:

```
dialroutel config>quarantine-time ?  
<2..60>    Quarantine time (minutes)  
dialroutel config>quarantine-time 4  
dialroutel config>
```

2.1.4 Configuring the IP address

Use the following command to add an IP address to the interface (common to all IP interfaces):

```
dialroutel config>ip address { <dirección_IP> | unnumbered }
```

Example:

To configure an IP address for the *Dial Routing* interface as unnumbered, enter the following:

```
dialroutel config>ip address unnumbered  
dialroutel config>
```

Note

For further information on configuring IP, please see Teldat manual Dm702-I TCP/IP Configuration.

2.1.5 Displaying the configuration

2.1.5.1 Listing the configuration common to all connections

Run the following command to list the configuration affecting all connections:

```
dialroutel config>list interface
```

Example:

```
dialroutel config>list interface  
Interface Configuration  
-----  
Pool Name:          POOL1  
Quarantine time:   4 min.  
dialroutel config>
```

2.1.5.2 Listing specific connection parameters

Run the following command to list the configured connections:

```
dialroutel config>list connection
```

Example:

```
dialroutel config>list connection  
Connections  
-----  
  
ID      Destination Address  Username  
-----  
      1  918076565          USUARIO1@teldat  
dialroutel config>
```

2.1.5.3 Listing all the configuration

Run the following command to list the whole of the configuration for this interface:

```
dialroutel config>list all
```

Example:

```
dialroutel config>list all  
Interface Configuration  
-----
```

```

Pool Name:          POOL1
Quarantine time:   4 min.

Connections
-----
ID      Destination Address  Username
-----  -----
1      918076565           USUARIO1@teldat
dialroute1 config>

```

2.1.6 Return to the previous menu

To exit the interface configuration menu and return to the main device configuration menu, run the following command (the same for all the device configuration):

```
dialroute1 config>exit
```

Example:

```
dialroute1 config>exit
Config>
```

2.2 ID Static Route Configuration Commands

This section describes all the commands used to configure the ID static routes. Run the following commands to access the IP configuration menu and the configuration environment for the routes:

```

*config

Config>protocol ip

-- Internet protocol user configuration --
IP config>

```

2.2.1 Adding a static route with identifier

Run the following command to add an ID static route:

```
IP config>id-route <dest> <mask> <next-gw> <id>
```

The parameters are, in this order, destination network, destination mask, next hop and identifier.

In the next hop parameter, enter the *Dial Routing* interface name, which contains the connection to reach said destination network.

Example:

```
IP config>id-route 2.2.2.2 255.255.255.255 dialroute1 25
IP config>
```

2.2.2 Deleting a static route with identifier

To delete an ID static route, run the following command:

```
IP config>no id-route <dest> <mask> <next-gw>
```

These parameters, in this order, are: destination network, destination mask and next hop.

Example:

```
IP config>no id-route 2.2.2.2 255.255.255.255 dialroute1
IP config>
```

2.2.3 Listing configured ID routes

Run the following command to list the configured static routes:

Syntax:

```
IP config>list routes
```

**Note**

The ID routes are those in the list that begin with "ID Route...." The rest are normal static routes.

Example:

```
IP config>list routes

route to 0.0.0.0,0.0.0.0 via 192.168.1.1, cost 1
ID route to 5.5.5.5,255.255.255.255 via dialroute1, Id 5
ID route to 3.3.3.3,255.255.255.255 via dialroute1, Id 3
ID route to 1.1.1.1,255.255.255.255 via dialroute1, Id 1
ID route to 192.80.0.120,255.255.255.255 via dialroute2, Id 2
IP config>
```

For further information on IP configuration, please see Teldat manual Dm702-I TCP/IP Configuration.

Chapter 3 Monitoring

3.1 Monitoring the Dial Routing Interface

This section describes the commands used to monitor the state of the *Dial Routing* interface links and connections. To access this monitoring, run the following commands:

```
*monitor
Console Operator
+network <interface_name>
-- Interface <interface_name> Console --
DR monitor+
```

Example:

```
*monitor
Console Operator
+network dialroute1
-- Interface dialroute1 Console --
DR monitor+
```

The following commands are available in the interface console:

Command	Function
? (AYUDA)	Lists the commands or their options.
LIST	Displays the <i>Dial Routing</i> interface monitoring information.
EXIT	Exits the interface monitoring console.

3.1.1 ? (HELP)

Use the **?** (**HELP**) command to list the commands available at the layer where the router is monitoring. You can also use this command after a specific command to list its options.

Syntax:

```
DR monitor+?
```

Example:

```
DR monitor+?
list      Show monitoring information
exit
DR monitor+
```

3.1.2 Displaying the monitoring information

On selecting **list**, view the available options by running **help**:

```
DR monitor+list ?
all           Information about links and connections
connections   Status of the Dial Routing connections
links         State of the participating PPP interfaces
DR monitor+
```

3.1.2.1 Monitoring information completed

To list the state of the PPP interfaces, participating in the *Dial Routing* process, and the status of the *Dial Routing* connections in an interface, run the following command:

Syntax:

```
DR monitor+list all
```

Example:

```
DR monitor+list all
```

```

Links status
-----
PPP Interface      Status          Connection ID
-----
ppp1              IDLE
ppp2              IDLE

Connections status
-----
Connection Id    Destination address   Username           Status
-----
1               918076565        USUARIO1@teldat       INACTIVE
DR monitor+

```

3.1.2.2 Connection Status

To list the status of the *Dial Routing* connections in an interface, run the following command:

Syntax:

```
DR monitor+list connections
```

Example:

```

DR monitor+list connections
Connections status
-----
Connection Id    Destination address   Username           Status
-----
1               918076565        USUARIO1@teldat       INACTIVE
DR monitor+

```

A list is displayed with an entry for each connection profile where you can see the identifier, the destination telephone number, the user name and whether it is being used by a link or not.

3.1.2.3 Link information

To list the state of the PPP interfaces (participating in the *Dial Routing* process directed by this interface), run the following command:

Syntax:

```
DR monitor+list links
```

Example:

```

DR monitor+list links
Links status
-----
PPP Interface      Status          Connection ID
-----
ppp1              IDLE
ppp2              IDLE
DR monitor+

```

This list contains an entry for each PPP interface that can be used by this Dial Routing interface to carry out a connection. The *Status* field indicates if the interface is active or available. When active, the *Connection ID* field indicates the identifier of the connection you are using.

If the link list contains less interfaces than expected, check the pool name configuration in the *Dial Routing* interface and the PPP interfaces.

3.1.3 Return to the previous menu

Run **exit** to leave the interface monitoring menu.

Syntax:

```
DR monitor+exit
```

Example:

```
DR monitor+exit
+
```

3.2 Monitoring the ID Static Routes

This section describes commands used to monitor the ID static routes. Run the following commands to access the monitoring menu for these routes:

```
*monitor
Console Operator
+protocol ip
IP+
```

The following table summarizes the static route ID monitoring commands.

Command	Function
DUMP-ROUTING-TABLE	Lists the active route table.
ROUTE-GIVEN-ADDRESS	Lists the next hop to a given destination.
STATIC-ROUTES	Lists the static route table.
EXIT	Returns to the previous prompt.

3.2.1 Active route table

Run **dump-routing-table** to display the active route table:

Syntax:

```
IP+dump-routing-table
```

Example:

```
IP+dump-routing-table
Type          Dest net/Mask   Cost Age  Next hop(s)

Stat(1) [0]      0.0.0.0/0  [ 60/1 ] 0    192.168.1.1 (ethernet0/0)
Sbnt(0) [0]      1.0.0.0/8  [240/1 ] 0    None

                                Stat(1) [0] 1.1.1.0/24 [ 60/3 ] 0 dialroute1

Sbnt(0) [0]      2.0.0.0/8  [240/1 ] 0    None

                                Stat(1) [0] 2.2.2.0/24 [ 60/3 ] 0 dialroute1

Sbnt(0) [0]      3.0.0.0/8  [240/1 ] 0    None

                                Stat(1) [0] 3.3.3.0/24 [ 60/3 ] 0 dialroute1

Sbnt(0) [0]      4.0.0.0/8  [240/1 ] 0    None

                                Stat(1) [0] 4.4.4.0/24 [ 60/3 ] 0 dialroute2

Sbnt(0) [0]      5.0.0.0/8  [240/1 ] 0    None

                                Stat(1) [0] 5.5.5.0/24 [ 60/3 ] 0 dialroute2

Sbnt(0) [0]      7.0.0.0/8  [240/1 ] 0    None
Dir(0) [1]        7.7.7.0/24 [ 0/1 ] 0    ethernet0/0
Dir(0) [1]        7.7.7.7/32 [ 0/1 ] 0    snk
Dir(0) [1]        192.168.1.0/24 [ 0/1 ] 0    ethernet0/0

Default gateway in use.
Type Cost Age  Next hop
Stat 1     0    192.168.1.1 (ethernet0/0)

Routing table size: 768 nets (64512 bytes), 15 nets known, 15 shown
IP+
```

The ID static routes are those shown in bold. These differ from the rest of the static routes in the next hop (dialrouteX), apart from that they are identical.

3.2.2 Calculating the next hop

Run **route-given-address** to display the next hop to a given destination.

Syntax:

```
IP+route-given-address <dest>
```

Example:

```
IP+route-given-address 1.1.1.1
Destination: 1.1.1.0
Mask: 255.255.255.0
Route type: Stat
Distance: 3
Tag: 0
Next hop(s): 1.1.1.1 (dialroute1) Age: 0
```

If the next hop to access a given destination is a *Dial Routing* interface, “dialrouteX” will appear in “Next hop”

3.2.3 Static route table

Run **static-routes** to view the configured static route table:

Syntax:

```
IP+static-routes
```

Example:

```
IP+static-routes
Flags: A added to routing table, R refresh, T track up
Type Net Cost Next_hop Int Circuit State
---- --- ---- ----- --- -----
CNFG 0.0.0.0/0 1 192.168.1.1 ethernet0/0 N/A Ar

CNFG 1.1.1.0/24 3 dialroute1 dialroute1 1 Ar
CNFG 2.2.2.0/24 3 dialroute1 dialroute1 2 Ar
CNFG 3.3.3.0/24 3 dialroute1 dialroute1 3 Ar
CNFG 4.4.4.0/24 3 dialroute2 dialroute2 4 Ar
CNFG 5.5.5.0/24 3 dialroute2 dialroute2 5 Ar
```

The ID static routes are highlighted in bold. These differ from the rest in the next hop (dialroute X) and in the circuit: the configured ID.
